Correlations of 6-minute walk distance (6MWD) with Subjective Measures of Dyspnea in Systemic Sclerosis (SSc) Patients.

University of Michigan, Ann Arbor, Michigan, United States.

Abstract

Background
The six minute walk distance (6MWD) is a standardized measure of submaximal exercise capacity and serves as a key outcome measure in many studies of pulmonary involvement. 6MWD is not fully validated in SSc patients definitions of minimally clinically important differences (MCID).

Purpose
To evaluate the correlation of the Δ 6MWD with Δ subjective outcome measures of lung disease in SSc patients and to explore the possibility of establishing an MCID for 6MWD based on changes in Borg dyspnea/fatigue indices (BDI, BFI).

Methods and Patients
119 SSc patients with multiple 6MWD were retrospectively identified. Data abstracted include 6MWD, BDI and BFI at rest and peak; and pulmonary function test results (PVC, DLco, TLC). Mean age was 56.1 yrs ± 12.1 and mean disease duration 8.2 yrs ± 7.6. 104 were female (87.4%), 81 (68.1%) were classified as Limited and 38 (31.9%) as diffuse SSc.

Results
(See table)
Mean interval between two 6MWD was 8.6 mins ± 7.3. The absolute mean Δ 6MWD was 45.05 m ± 39.85 (range 187.8 to 193.5). BDI and BFI remained fairly stable between tests (e.g., mean Δ BDI Peak: -0.17 ± 1.68; mean Δ BFI Peak: -0.65 ± 1.88). Mean absolute Δ % of predicted PVC was 5.41 ± 4.47 (range -17 to +23); % of predicted DLco was 5.71 ± 3.35 (range -16 to +23); and % of predicted TLC was 6.1 ± 4.65 (range -14 to +21). The following significant correlations between Δ 6MWD and other Δ measures were found: 0.46 with PVC (p<0.05); 0.34 (p<0.05) with DLco, and -22 for BDI Peak (p<0.05).

Conclusions
6MWD was designed as a measure of submaximal functional ability representative of activities of daily living. Borg scales, measuring perceived exercise exertion, is strongly influenced by multiple psychophysical functions reflecting the "Gestalt of perceived exertion" (Borg G. Med Sci Sports Exer 1982; 14: 377). Both measures have been used as surrogate for lung functioning but never fully validated in SSc. In the present study, 6MWD and Borg PE changed reliably with disease activity.

Introduction

6MWD is a simple standardized measure of submaximal exercise capacity.

Used in clinical trials of pulmonary involvement in SSc but its utility as outcome measure is not fully validated.

- Goal of study: establish MCID for 6MWD.

Methods

Subjects
- Patients with diagnosis of SSc by ACC classification criteria with 2 or more 6MWD. Presented are data for 119 patients with 2 6MWT
- Retrospective study
- Patient characteristics:
  - 81 (68.1%) with Limited and 38 (31.9%) with diffuse SSc
  - Age: 56.1 yrs ± 12.1
  - Gender: 104 (87.4%) females
  - Duration of Disease: 8.2 yrs ± 7.6

Data:
1) 6 MWT
2) Pulmonary Function Test (PVC, DLco, TLC)
3) Borg Dyspnea and Fatigue Index at Rest and at Peak

Conclusions

6 Minute Walk Test/ Borg:
- 6 MWT is designed as a measure of submaximal functional ability representative of activities of daily living.
- Borg scores perceived exercise exertion and is influenced by several psychophysical functions reflecting the “Gestalt of perceived exertion” (Borg G. Med Sci Sports Exer 1982; 14: 377).
- Both measures used as surrogate for lung function in SSc but not yet fully validated.

6 Minute Walk Test/ Borg/PTF:
- All measures were reliably stable over time but ranges were large.
- No association was found between change in mean distance walked and change in the Borg Indices.
- Borg Indices appear insensitive to change and seemingly lack construct and content validity.

Findings do not support establishment of MCID in 6MWD based on Borg Indices.

Results

Mean Δ 6MWD change per unit Δ Borg for Peak Dyspnea and Fatigue Indices were:
